RL - Reinforcement Learning (Aprendizaje por Refuerzo)

- Reinforcement Learning es un conjunto de modelos y algoritmos que permiten resolver problemas de tomas de decisiones.
- Se enfocan en obtener el conjunto de acciones que permitan obtener la mejor salida posible.
- A diferencia de los modelos de aprendizaje supervisado, en estos casos no hay una solución inequívoca o una única respuesta correcta.
- Ejemplos
 - En una partida de ajedrez, no existe un único conjunto de movimientos que permita ganar una partida.
 - Si queremos que un robot cuadrúpedo camine, no tenemos conocimiento previo de cuáles son las acciones correctas que le permitan caminar.
 - [DeepMind](#)

Elementos principales de modelos RL

- **Agente:** Es el elemento encargado de la toma de decisiones. Además es el responsable de aprender qué acciones tomar para lograr el mejor resultado.
- **Entorno:** Es el mundo en el que opera el agente. Este puede ser real, virtual o cualquier otro elemento con el que el agente interactúe.

- **Acciones:** Cada agente puede realizar acciones las cuales les permiten interactuar con su entorno.
- **Estado:** Corresponde a una representación del entorno en un cierto momento. El agente utiliza el estado como contexto para la toma de decisiones y sus correspondientes acciones
- **Recompensa:** Las recompensas son recibidas por el agente desde el entorno en base a cada acción tomada. Las recompensas pueden ser positivas o negativas en base a un objetivo
- **Política:** La política es una estrategia que el agente sigue para decidir qué acciones tomar en función de su estado actual. El objetivo del agente es aprender una política óptima que le permita obtener la máxima recompensa posible a lo largo del tiempo.

Formalización a través de Procesos de decisión de Markov

Definimos un Proceso de Decisión de Markov (Markov Decision Process) como una tupla $(S, A, \{P_{sa}\}, \gamma, R)$ donde

- S es el conjunto estados en que se puede encontrar el entorno
- A es el conjunto de acciones posible que puede realizar el agente
- P_{sa} son las probabilidades de transición entre estados. Estas se definen para cada estado $s \in S$ y acción $a \in A$. En otras palabras, es la distribución de probabilidades sobre cada estado s al tomar una acción a .
- $\gamma \in [0, 1)$ es el factor de descuento
- $R : S \times A \rightarrow \mathbb{R}$ es la función de recompensa. En ocasiones se escribe como una función solo dependiente del estado, en cuyo caso se anota como $R : S \rightarrow \mathbb{R}$

Las dinámicas de un proceso de Markov quedan definidas de la siguiente manera:

- Se define un estado inicial $s_0 \in S$, a partir del cual se toma una acción $a_0 \in A$.
- Resultado de la decisión a_0 , se transiciona aleatoriamente a un estado s_1 donde $s_1 \sim P_{s_0 a_0}$.
- A partir del estado s_1 , se toma una nueva decisión a_1 .
- La decisión a_1 genera una transición aleatoria a un nuevo estado $s_2 \sim P_{s_1 a_1}$

$$s_0 \xrightarrow{a_0} s_1 \xrightarrow{a_1} s_2 \xrightarrow{a_2} s_3 \xrightarrow{a_3} \dots$$

Para este caso la recompensa total puede ser definida como

$$R(s_0, a_0) + \gamma R(s_1, a_1) + \gamma^2 R(s_2, a_2) + \dots$$

o, reescribiendo como función dependiente de los estados

$$R(s_0) + \gamma R(s_1) + \gamma^2 R(s_2) + \dots$$

El objetivo del aprendizaje por refuerzo es **determinar el conjunto de acciones que maximizan la esperanza de la recompensa**

$$E[R(s_0) + \gamma R(s_1) + \gamma^2 R(s_2) + \dots]$$

- Considere una función de política $\pi : S \rightarrow A$, la cual mapea cada estado a una acción. Es posible definir la recompensa obtenida en base a esa política y un cierto estado inicial como

$$V^\pi(s) = E[R(s_0) + \gamma R(s_1) + \gamma^2 R(s_2) + \dots | s_0 = s, \pi]$$

- Esta puede ser reescrita en su forma de "ecuación de Bellman" como sigue

$$V^\pi(s) = R(s) + \gamma \sum_{s' \in S} P_{s\pi(s)}(s') V^\pi(s')$$

Mundo Grilla

Consideremos el siguiente caso.

- Movimientos posibles: Arriba ($\uparrow$), abajo ($\downarrow$), izquierda ($\leftarrow$) y derecha ($\rightarrow$)
- Casillas +1 y -1 corresponden a las casillas de salida con recompensas del mismo valor
- Objetivo: terminar el juego con la mayor puntuación posible

			+1
			-1
START			

Se define la siguiente política π para cada estado de la grilla

→	→	→	+1
↑		↑	-1
↑	→	↑	←

Mundo Grilla (caso determinista sin descuento)

- Mejores movimientos desde inicio: $\uparrow, \uparrow, \rightarrow, \rightarrow, \rightarrow$

V=1	V=1	V=1	+1
V=1		V=1	-1
START	V=1	V=1	V=1

Mundo Grilla (caso determinista con descuento)

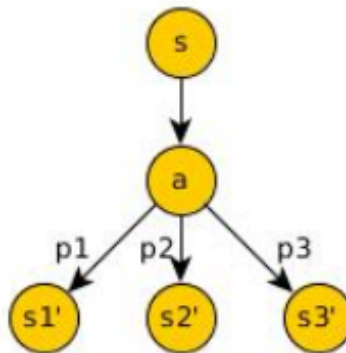

$$\gamma = 0.9$$

V=0.81	V=0.9	V=1	+1
V=0.73		V=0.9	-1
START	V=0.73	V=0.81	V=0.73

- Los casos anteriores representan situaciones deterministas donde cada acción a realizar por el agente tiene un 100% de probabilidad de éxito (sin errores).
- La ecuación de Bellman permite también considerar casos en donde el agente puede cometer errores.

Determinista

Estocástico

Considere ahora que los movimientos del agente no son confiables, es decir **tienen cierta probabilidad**. Considere las siguientes probabilidades

- 80% de ir a la dirección deseada
- 10% de ir a la izquierda de la dirección deseada
- 10% de ir a la derecha de la dirección deseada

Ejemplo:

- $P(\uparrow | \uparrow) = 0.8, P(\leftarrow | \uparrow) = 0.1, P(\rightarrow | \uparrow) = 0.1$

¿Cómo podemos calcular las recompensas de cada casilla? R: Algoritmo Value Iteration

?	?	?	+1
?		?	-1
START	?	?	?

Algoritmo Value Iteration

- Para cada estado s , inicializar $V(s) := 0$
- Repetir hasta la convergencia lo siguiente
 - Por cada estado, actualizar $V(s) := R(s) + \max_{a \in A} \gamma \sum_{s'} P_{sa}(s') V(s')$

Esto no solo permite calcular los valores de recompensa esperada por cada estado, sino que también permite obtener la mejor política para el conjunto de estados (policy iteration)

- Inicializar π aleatoriamente
- Repetir hasta la convergencia lo siguiente
 - Por cada estado s $\pi(s) := \operatorname{argmax}_{a \in A} P_{sa}(s') V(s')$

Q Learning

- Hasta el momento, hemos supuesto que las recompensas y las probabilidades de acción son conocidas. ¿Cómo cambia nuestro planteamiento si no conocemos estos datos?
- En ese caso, debemos descubrir sus valores en base a la **experiencia** (muestras).

- Para ello calcularemos para cada combinación de estado/acción cuáles son las recompensas esperadas en base a las muestras (valores Q). Estos se calculan con la siguiente fórmula

$$Q(s, a) := Q(s, a) + \alpha [R(s, a) + \gamma \max_a \{Q(s', a')\} - Q(s, a)]$$

Donde encontramos la siguiente relación entre los valores Q y los elementos previamente calculados

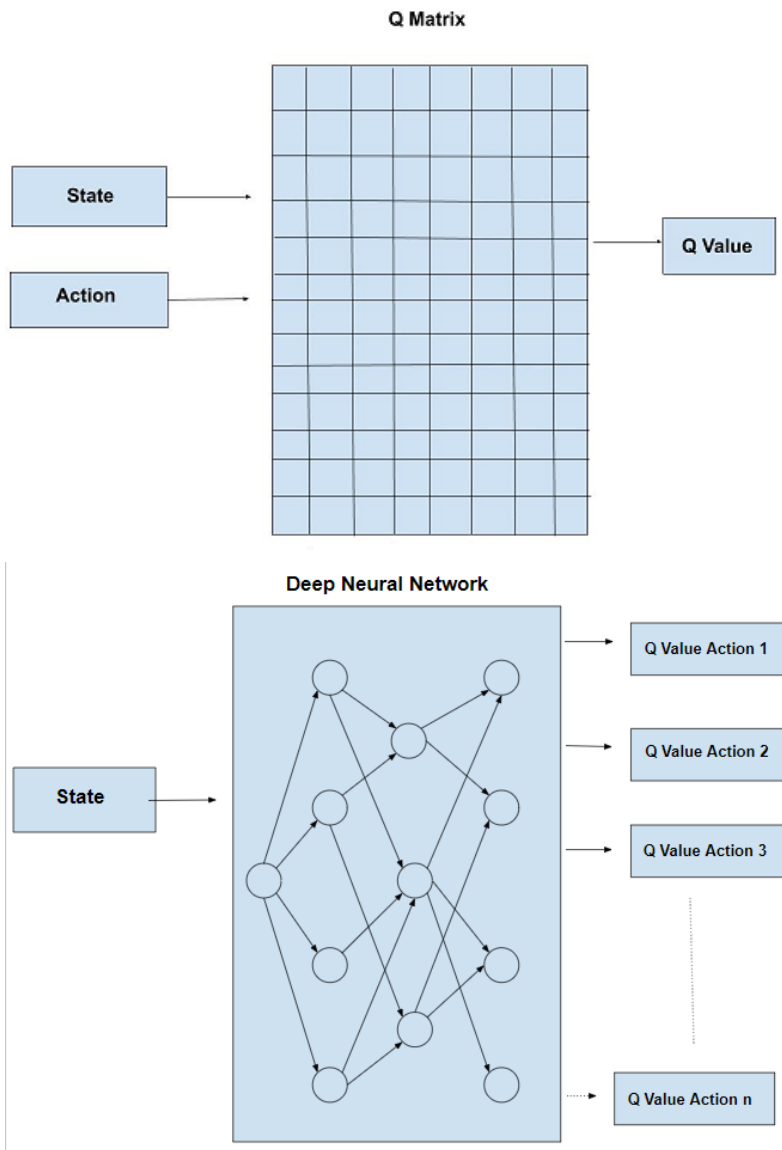

$$V(s) = \max_a (R(s, a) + \gamma \sum_{s'} P_{sa}(s') V(s')) = \max_a (Q(s, a))$$

$$\pi(s) = \max_a (Q(s, a))$$

- Q viene de quality, pues mide la calidad de las acciones que tomamos a partir de un cierto estado.

Deep Q Learning

- Si bien, el modelo Q Learning funciona correctamente, no escala bien en relación a la cantidad de estados y acciones.
- Por ello, se plantean los modelos de redes neuronales como alternativa para la obtención de los valores Q (Deep Q Learning).
- Los valores obtenidos por el algoritmo Q Learning, son utilizados como base para una red neuronal. Esta red neuronal recibe como entrada los valores del estado del entorno, y retorna los valores Q para todas las acciones disponibles.

Source: <https://www.geeksforgeeks.org/deep-q-learning/>

Funcionamiento

- Considere un Q-Value obtenido por la red neuronal DQN para un par (s, a) de estado y acción.
- Gracias a la ecuación de Bellman, sabemos que es posible aproximar el Q-Value y hacerlo lo más cercano posible a la recompensa R observada en para ese estado y acción más el Q-Value de la mejor acción a partir de ese punto.

$$Q_{\text{target}}(s, a) = R(s, a) + \gamma Q_{\theta}(s', a')$$

- Esto es lo que usaremos como target en cada caso en nuestra red neuronal.

OpenAI Gymnasium

- Biblioteca Python de OpenAI (originalmente llamada Gym)
- Permite con una interfaz sencilla interactuar con diferentes entornos para la prueba de modelos de Aprendizaje por Refuerzo utilizando una API común para todos ellos.
- Se puede instalar en un entorno virtual a través de pip con `pip install gymnasium`
- Gymnasium posee múltiples entornos los que se pueden instalar manualmente. Si desea instalarlos todos, puede hacerlo a través del comando pip a continuación:
`pip install gymnasium[all]`
- Documentación disponible [aquí](#)

Ejemplo de uso Gymnasium

```
In [2]: # Se importa la biblioteca
import gymnasium as gym
# Se crea uno de los entornos a través de make
# Se puede obtener un renderizado del juego a través de
# .make("EnvName", render_mode="human")
env = gym.make("CartPole-v1", render_mode="human")

# Una vez creado el entorno, obtenemos el estado inicial (primera observación)
# usando env.reset()
observation, info = env.reset()

# El entorno mantiene almacenado los valores posibles tanto de acciones como
# Las acciones se mantienen en env.action_space y las observaciones en env.observation_space
for _ in range(300):
    # Probamos nuestro entorno con acciones aleatorias
    # A partir del action_space obtenemos una muestra de una acción
    action = env.action_space.sample() # agent policy that uses the observation

    # Utilizamos esa acción para el siguiente step de evaluación. Como resultado
    # obtenemos una nueva observación del estado del entorno y una recompensa
    # Las variables terminated y truncated determinan el final de la prueba,
    # ya sea por un estado final o se ha truncado la ejecución
    observation, reward, terminated, truncated, info = env.step(action)
    if terminated or truncated:
        observation, info = env.reset()

# Finalmente cerramos el entorno al terminar la ejecución
env.close()
```

```
